

Let us assume that we have 2 wells A i B or more precisely 2 quantum systems A and B.

In such case the total Hamiltonian of the system is

$$H_A(t) = E_A(t) |A\rangle\langle A| \text{ and } H_B(t) = E_B(t) |B\rangle\langle B|.$$

If we consider the interaction between A and B we write it as $H_{AB} = E_{int}(t)(|A\rangle\langle B| + |B\rangle\langle A|)$.

However in general case we shall consider even more generalized interaction term

$$H_{AB1} = E_{int1}(t) [f_1(|A\rangle\langle B|)(|B\rangle\langle A|) + (|A\rangle\langle B|)(\langle A|\langle B|) f_2 + f_3(|A\rangle\langle B|)(|B\rangle\langle B|) + f_4(|A\rangle\langle B|)(|A\rangle\langle A|) + f_5(|B\rangle\langle A|)(|A\rangle\langle A|) + f_6(|B\rangle\langle A|)(|B\rangle\langle B|) + f_7(|A\rangle\langle B|)(|B\rangle\langle A|) + f_72(|B\rangle\langle A|)(|A\rangle\langle B|)].$$

All functions $f_1, \dots, f_6, f_7, f_72$ has deeper physical meaning in regards to self fields etc. At first we neglect H_{AB1} term of Hamiltonian.

Thus total Hamilton of the system (A and B) is $H = H_A + H_B + H_{AB}$ and thus we have

$H = E_A(t) |A\rangle\langle A| + E_B(t) |B\rangle\langle B| + E_{int}(t)(|A\rangle\langle B| + |B\rangle\langle A|)$. The strength of interaction can be arbitrary so it might happen that $E_{int} \gg E_A, E_B$ so it is non-perturbative interaction or perturbative if $E_{int} \ll E_A, E_B$ or E_{int} , E_A and E_B can have any values.

At first let us assume for the simplicity that A system has (at least) two eigenstates that are orthogonal so $\langle A_1 | A_2 \rangle = 0$.

In such case $|A\rangle = a_1 |A_1\rangle + a_2 |A_2\rangle$. Normalization condition requires $\langle A | A \rangle = 1$. (number of particles in the system A is preserved).

In similar fashion we can assume that B system has (at least) two eigenstates that are orthogonal so $\langle B_1 | B_2 \rangle = 0$. Normalization condition requires $\langle B | B \rangle = 1$ (number of particles in the system B is preserved).

In such case $|B\rangle = b_1 |B_1\rangle + b_2 |B_2\rangle$. Complex conjugate of a_1 we denote as a_1^* , etc ...

Thus we have

$$|A\rangle\langle B| = (a_1 |A_1\rangle + a_2 |A_2\rangle)(b_1^* \langle B_1| + b_2^* \langle B_2|) = a_1 b_1^* |A_1\rangle\langle B_1| + a_2 b_2^* |A_2\rangle\langle B_2| + a_1 b_2^* |A_1\rangle\langle B_2| + a_2 b_1^* |A_2\rangle\langle B_1|,$$

and

$$|B\rangle\langle A| = (b_1 |B_1\rangle + b_2 |B_2\rangle)(a_1^* \langle A_1| + a_2^* \langle A_2|) = b_1 a_1^* |B_1\rangle\langle A_1| + b_2 a_2^* |B_2\rangle\langle A_2| + b_1 a_2^* |B_1\rangle\langle A_2| + b_2 a_1^* |B_2\rangle\langle A_1|.$$

and

$$|A\rangle\langle A| = (a_1 |A_1\rangle + a_2 |A_2\rangle)(a_1^* \langle A_1| + a_2^* \langle A_2|) = a_1 a_1^* |A_1\rangle\langle A_1| + a_2 a_2^* |A_2\rangle\langle A_2| + a_1 a_2^* |A_1\rangle\langle A_2| + a_2 a_1^* |A_2\rangle\langle A_1|,$$

and

$$|B\rangle\langle B| = (b_1 |B_1\rangle + b_2 |B_2\rangle)(b_1^* \langle B_1| + b_2^* \langle B_2|) = b_1 b_1^* |B_1\rangle\langle B_1| + b_2 b_2^* |B_2\rangle\langle B_2| + b_1 b_2^* |B_1\rangle\langle B_2| + b_2 b_1^* |B_2\rangle\langle B_1|.$$

Thus total Hamiltonian can be written as

$$\begin{aligned}
H = & E_a(a_1 |1\rangle\langle 1| + a_2 |2\rangle\langle 2| + a_1 a_2^* |1\rangle\langle 2| + a_2 a_1^* |2\rangle\langle 1|) + \\
& + E_b(b_1 |1\rangle\langle 1| + b_2 |2\rangle\langle 2| + b_1 b_2^* |1\rangle\langle 2| + b_2 b_1^* |2\rangle\langle 1|) + \\
& + E_{int}(a_1 b_1^* |1\rangle\langle 1| + a_2 b_2^* |2\rangle\langle 2| + a_1 b_2^* |1\rangle\langle 2| + a_2 b_1^* |2\rangle\langle 1|) + \\
& + E_{int}(b_1 a_1^* |1\rangle\langle 1| + b_2 a_2^* |2\rangle\langle 2| + b_1 a_2^* |1\rangle\langle 2| + b_2 a_1^* |2\rangle\langle 1|).
\end{aligned}$$

It shall be underlined that system A can have more than 2 levels and for example N_a eigenstates. It shall be underlined that system B can have more than 2 levels and for example N_b eigenstates. In particular $|A(B)1\rangle = |1a(b)\rangle$ (spin-up in A(B) system) and $|A(B)2\rangle = |2a(b)\rangle$ (spin-down in A (B) system). However we do not need to limit ourself to spin.

We can notice that in order to obtain the state close to one of the Bell state $|\psi\rangle = (c_1 |1\rangle|2\rangle + c_2 |2\rangle|1\rangle)$ we need to promote terms in total Hamiltonian with operators $|1\rangle\langle 2|$ and $|2\rangle\langle 1|$ by increasing certain coefficient and decreasing another coefficients.

In order to obtain entanglement we need to bring systems A and B close and make strong interaction of them and later take them away. Once they are separated and measurement is taken on one of the subsystems A (or B) „spooky action on the distance” might take place on B (A system). In such way get the EPR paradox or violation of Bell inequality. The entanglement take place with proper engineering of interaction by proper biasing of various gates present in the system.

Concrete computations and examples are yet to be given .

In similar way we can conduct the reasoning for A, B and C systems. In principle we can treat in this way N interacting systems (N particles) coming from N wells. Thus we can end up with entanglement of N particles.

More rigorous treatment of system dynamics with time includes more detailed description of decoherence and various non-equilibrium techniques. It then requires the use of Keldysh Green functions .
